Title : SERVING DYNAMIC WEB-PAGES

Mail Stop Appeal Brief - Patents

Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

DECLARATION OF BENJAMIN W. WYCKOFF UNDER 37 C.F.R. 1.131

I, Benjamin W. Wyckoff, hereby declare:

1. That I am a co-inventor of the claims in the above-captioned patent application.
2. That in an Office Action dated July 18, 2006, certain claims were rejected as being unpatentable over *Ima*, et al., US2004/0230747, which has a priority date of July 6, 2000.
3. That on or before July 6, 2000, in the United States, a WTO member country, we conceived a method for enabling the generation of an updated web-page for storage in one of a plurality of cache servers, the method comprising: implementing programmable rules executing on each of the plurality of cache servers, each programmable rule defining a triggering event associated with its corresponding cache server, the occurrence of the triggering event being indicative of the existence of an obsolete portion of the web-page stored in the corresponding cache server; detecting an occurrence of a triggering event at a particular cache server selected from the plurality of cache servers; in response

to the occurrence of the triggering event, causing the particular cache server to request an update of the obsolete portion; and receiving an updated portion of the web-page for storage at the particular cache server.

4. That on or before July 6, 2000, in the United States, a WTO member country, we conceived of a computer-readable medium having encoded thereon software for updating web-pages stored in caches, each cache being associated with a corresponding cache server from a plurality of cache serves, the software comprising instructions for implementing programmable rules executing on each of the plurality of cache servers, each programmable rule defining a triggering event associated with its corresponding cache server, the occurrence of the triggering event being indicative of the existence of an obsolete portion of the web-page stored in the corresponding cache server; detecting an occurrence of a triggering event at a particular cache server selected from the plurality of cache servers; in response to the occurrence of the triggering event, causing the particular cache server to request an update of the obsolete portion; and receiving an updated portion of the web-page for storage at the particular cache server.
5. That on or before July 6, 2000, in the United States, a WTO member country, we conceived of a web-serving system comprising a plurality of cache servers each having a corresponding cache memory; and a cache manager in communication with the corresponding cache memory for controlling content of the corresponding cache memory, the cache manager being configured to execute a programmable script, the script being configured for detecting the occurrence of a triggering event, and in response to detection of the triggering event, causing the cache manager to request an update of the content of the cache memory.
5. That as evidence of my conception, I have enclosed herewith:

Exhibit A, which is a copy of the first six pages of an email string provided to a private focus group of users who agreed to assist us in testing our invention, which we named "DBFX;"

Exhibit B, which is a copy of the first four pages of a document I prepared to describe architecture notes and design and implementation decisions for DBFX;

Exhibit C, which is a copy of the first four pages of a document I prepared to describe certain environmental variables, script tags, and attribute names used during processing of DBFX scripts; and

Exhibit D, which is an exemplary DBFX script.

6. The following table sets forth support for the features of the invention claimed in independent claim 1 and the corresponding features in independent claim 18.

CLAIM LIMITATION	SUPPORT FOR CONCEPTION
A method for enabling the generation of an updated web-page for storage in one of a plurality of cache servers, said method comprising:	
implementing programmable rules executing on each of the plurality of cache servers, each programmable rule defining a triggering event associated with its corresponding cache server, the occurrence of the triggering event being indicative of the existence of an obsolete portion of said web-page stored in said corresponding cache server;	<p>Exhibit A: page 6 "There's even a simple IF-ELSE-ENDIF syntax, so you can make up your own rules."</p> <p>Exhibit A: page 2, "DBFX is extremely flexible in letting you create intelligent cache-management rules that keep all your queries and databases in sync."</p> <p>Exhibit A, page 2: "DBFX lets you transparently forward database queries from your main server to a second server."</p> <p>Exhibit B: page 3, bottom of page "DBFX is controlled by real or synthesized "DBFX files" which contain instructions for modifying the request environment and specifying the action to take.</p> <p>Exhibit C: page 2, see syntax for "IF" at bottom of page.</p>

detecting an occurrence of a triggering event at a particular cache server selected from the plurality of cache servers;	This would be whatever condition is specified in any of the "IF" statements above. For example, see Exhibit A: page 5, "You can easily set up any combination of: - specify a fixed amount of time to cache". See also Exhibit D sample "if" statements.
in response to the occurrence of said triggering event, causing said particular cache server to request an update of said obsolete portion; and	Exhibit D "decache" command executed. See also Exhibit A, page 5 referring to pre-cache and de-cache instructions, as well as ability to include or exclude any subset of queries from DBFX caching or processing. Exhibit B, page 4 "The [DBFX] file may also specify that DBFX should retrieve the data, flush the data, issue a redirect, etc."
receiving an updated portion of said web-page for storage at said particular cache server.	See Exhibit A page 5. This is the natural consequence of the retrieve option specified in Exhibit B, page 4.

7. The following table sets forth support for the features of the invention claimed in independent claim 13.

CLAIM LIMITATION	SUPPORT FOR CONCEPTION
A web-serving system comprising:	
a plurality of cache servers each having a corresponding cache memory; and	Prior art, needs no evidence of conception.
a cache manager in communication with said corresponding cache memory for controlling content of said corresponding cache memory, said cache manager being configured to execute a programmable script, said script being configured for detecting the occurrence of a triggering event, and in response to detection of said triggering event, causing said cache manager to request an update of said content of said cache memory.	Cache manager is whatever executes the script referred to in claim 1.

8. That on or before July 6, 2000, in the United States, a WTO member country, we reduced our invention to practice by writing software for carrying out the method steps recited in claim 1, encoding the software into a computer readable medium as recited in claim 19, and testing it on a system as recited in claim 13.
9. The dates in Exhibits A, B, C, and D have been redacted, however all the redacted dates were on or before July 6, 2000.
10. I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true. I further declare that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, under Section 1001 of Title 18 of the United States Code, and that such willful false statements may jeopardize the validity of the application or any patent issuing thereon.

WELCOME!

Welcome to the private Focus Group for ClearWay Technologies' new accelerator for Web database publishing, codenamed "DBFX"

DBFX speeds Web database queries, and gives you powerful, and flexible new options for how you publish your databases on the Web.

YOU ARE NOW PART OF THE FOCUS GROUP

You have been added to the DBFX-Beta mailing list because you asked to be added, or because you expressed an interest in a product that accelerates Web database publishing.

This small, closed mailing list will be used to tell you where to download the new software, and for discussions of how to use it for your database-publishing applications.

NON-DISCLOSURE

By electing to participate in this focus group, you will be in possession of proprietary, confidential, and trade secret information belonging to ClearWay Technologies, Inc. You must not disclose the content, or the nature, or character of the information discussed here to any third party without prior written consent from ClearWay Technologies, Inc. The sole exception is information that you are in prior possession of, or that becomes public through other means. You will be held liable for all damages arising

directly or indirectly from your actions if you disclose protected information

If you cannot abide by this plain-language non-disclosure agreement, contact me at once at <kriegsman@clearway.com> and you will be removed from the focus group and this mailing list.

WHAT THE DBFX SOFTWARE DOES

DBFX provides four new functions for your Web database:

1. Caching. The results of the most frequently/recently requested queries are cached, greatly speeding publishing applications using a database. DBFX is extremely flexible in letting you create intelligent cache-management rules that keep all your queries and databases in sync.
2. Virtual Queries. DBFX lets you create virtual URL hierarchies that actually translate into database queries. This allows you to hide the structure and nature of your database system, and can allow Web crawlers to index your databased content.
3. Forwarding. DBFX lets you transparently forward database queries from your main server to a second server, via TCP/IP. This allows you to move your database to a second computer without exposing the 'inner' structure to the outside world.
4. Data Insertion. DBFX lets you embed data from your databases on any NetCloak or WebSTAR SSI page with a few simple tags. Thus, you could use SSI for a rotating-ad-banner system, and still serve Web content from your database through the extremely fast DBFX cache.

DBFX works with: Lasso, Tango, WebCatalog, WebFM, FileMaker, and other popular Web databases. It's a WebSTAR plug-in, and will also be available for WebTen and other W*API-compatible servers. An Apache version is also in the works.

That's it in a nutshell. If you are doing "Web Database Publishing", then DBFX will probably make your job easier, and your Web site run much faster.

If you are using a Web database only for a highly-interactive application (such as a shopping cart system), DBFX will not accelerate it, but you may want to look at the other features as well.

HOW AND WHEN DO I GET THE SOFTWARE?

The software will be available for download later this week. You will be informed on this mailing list.

We expect every member of the focus group to be an active participant in this discussion and the refinement of DBFX. If you cannot spare the time (a few hours a week, for about four weeks), or if you will not have any opportunity to try DBFX, or if you simply don't want to do this now, just drop me an e-mail.

DON'T WANT TO BE PART OF THE FOCUS GROUP?

If you wish to be removed from the focus group, e-mail me directly at <kriegsman@clearway.com> You cannot remove yourself.

OK- Welcome to the list, and thank you for helping us out.

I hope that all this sounds interesting to you, and if it does, I'm sure you have a million questions... anyone want to kick off the discussion based on the four features identified above (Caching, Forwarding, Virtual Queries, Data Insertion) ?

I'm waiting for "how does it know how long to keep a query cached?" !

how does it know how long to keep a query cached?

;-)

Very excited about the next CWKA (Clearway killer app)

Also, note, the return address i missing the "r" in clearway
(dbfx-beta@clearway.com)

/Jocke

Good question! You can configure DBFX to cache queries as long (or as short, or as intelligently) as you wish.

You can easily set up any combination of:

- specify a fixed amount of time to cache (can vary per query, and globally) such as "one hour by default, but only 5 minutes for one special page"
- specify that when a query says "action=insert" (or anything else you wish), that DBFX will then flush any cached records from that same database. This lets you 'trap' any INSERT, UPDATE, and DELETE events that happen through Web-based interfaces.
- de-cache and/or pre-cache certain queries when the _Web_server's_ caches are flushed
- respect or ignore the "Expires" date in the original query result
- respect or ignore any No-cache directives in the browser request
- de-cache and/or pre-cache any queries you wish when a specific URL is requested (and you can defined any number of URLs for controlling the cache any way you wish...)
- include or exclude any set or subset of your queries from DBFX caching or processing; DBFX only caches queries you designate

There's even a simple IF-ELSE-ENDIF syntax, so you can make up your own rules.

Hopefully, this will all be clearer with the software in front of you. But the general concept is that you can specify with great ease and flexibility how long you want each query cached.

And thanks for asking, Joakim.

-Mark

WOW!

That is definitely more advanced then what I was looking for on
Lasso-Talk almost a year ago, I quote myself:

As one who is a sucker for "semi-dynamic" publishing solutions a
LARGE cache in Lasso would be great.

A typical url in one of our systems point to a formatfile with a
inline that uses the form_param to retrieve the article (ie:

DBFX Design Notes.txt
Ben Wyckoff

This document contains some architecture notes and design and implementation decisions for DBFX.

Server/Client Model Theory

(This is classic middleware)

DBFX is based internally on a Server/Client Model. The primary task of DBFX is to SERVE pages to clients making requests to the web server. Internally, DBFX turns around and acts as a CLIENT, getting data from a variety of other sources.

As a server, DBFX may get requests in a number of ways, including, but not limited to, as a W*API Plug-In in the CGI role, as a PIXO source or processor, and as a W* SSI Tag handler.

As a client, DBFX may get data in a number of ways, including, but not limited to, PIXO to other plug-ins running in the same server, TCP/IP to the same server or other servers (running anywhere), W* SSI specific services, Apple Events to CGI's, FastCGI.

The internal architecture turns the various requests contexts into a normalized request parameter block, with most of the data stored in an Environment data structure (PassiveVarEnv). Similarly, returning data back to the clients is hidden through use of an abstract Emitter object. This way, regardless of the request method (e.g., PIXO, W*API CGI), we can process the request in the same way after normalizing it. The REQUEST code is new to DBFX, but based on existing code, technology, and concepts.

The client code is handled in a similar way, with much of the code borrowed from the FireSite client technology. An HTTPRequest class (and its derived classes) provides a uniform interface to performing HTTP requests and handling the responses. Current clients support TCP/IP and PIXO. Extending the functionality to include AppleEvents or other methods is relatively straightforward, and does not alter the architecture of the system at all.

Server/Client Model Implementation

This section describes the architecture in terms of the specific classes and flow of control.

Request classes:

```
class DBFXRequestPB (virtual base class)
  class DBFXCGIRequestPB : public DBFXRequestPB
  class DBFXPIXOResultPB : public DBFXRequestPB
  class DBFXSSIResultPB : public DBFXRequestPB
```

Emitter classes:

```
(These may change, depending on how the cache is implemented)
class SimpleEmitter
  class WSAPIEmitter : public SimpleEmitter
  class BufferedEmitter : public SimpleEmitter
```

Client classes:

```
(There are a few levels here, to take advantage of existing code)
class DBFXClient
  class DBFXSimpleHTTPClient : public DBFXClient (prototype/test class)
  class DBFXHTTPRequestClient : public DBFXClient
```

Client classes, level 2:

```
(class DBFXHTTPRequestClient manages different HTTPRequest derived classes)
class HTTPRequest
  class HTTPRequestTCP : public HTTPRequest
  class HTTPRequestPIXO : public HTTPRequest
```

The basic flow is as follows:

Request_Entry_Point

```
custom entry point processing
create appropriate derived class of DBFXRequestPB
call DBFXRequestPB.ProcessRequest()
  InitializeEnv(serverField);
  PopulateEnv();
  RunDBFXInterpreter();
  Execute(0);
  // Note - cache hits will (probably) be processed here
  based on Env, prepare a new request, allocate new client class,
  execute the request, and the result is written to the emitter
  on the DBFXRequestPB.
  Emitter().flush();
```

// Note - cache insertion will (probably) happen here.
 perform custom request cleanup
 (may include actually handing data back to client, if not streaming)
 custom entry point exit-processing

Some specific entry points that are currently implemented are as follows:

PIXO Server:

```
PIXO_RunResult PIXOEntry(void * pixoPB);
    cast pixoPB to appropriate type
    create thread context
    call PIXOAction(pixoPB)
    if(status request)
        return OKToRun
    else {
        get server header field for responses
        DBFXPIXORequestPB dbfx(pixoPB);
        dbfx.ProcessRequest(serverField);
        // the response is buffered by the Emitter, because PIXO works in "page
mode"
        pixoResult = dbfx.StoreResultOnPIXOPB();
    }
    return pixoResult
handle exceptions
return pixo_result
```

W*API CGI Role Server:

```
WSAPI_Dispatch
    if(WSAPI_Run) {
        ProcessRunCall (commandPtr);
        get server header field for responses
        if admin request, handle directly
        DBFXCGIRequestPB dbfx(pb);
        dbfx.ProcessRequest(serverField);
        // the response is streamed back to the client by the Emitter as it is
generated
        return WSAPI_I_NoErr;
    }
```

DBFX "Command" Files

DBFX is controlled by real or synthesized "DBFX files" which contain instructions for modifying the request environment and specifying the action to take.

Specifically, a DBFX file might set the host name, scriptname, path and search args describing the location of the desired content. The file may also specify that DBFX should retrieve the data, flush the data, issue a redirect, etc.

As a DBFX server receives a request, it populates an environment with the request parameters. The original request may identify a physical DBFX file on disk. If so, the file contents are parsed, with the tag-handler side effects possibly modifying the request environment. Also, the original request (e.g., for PIXO or SSI) may include DBFX commands in the request, so there is no physical file to load. In this case, the commands are similarly processed for side effect. Lastly, there may be global rules applied to the request, which may result in some other DBFX file or command set to be processed. For instance, a "virtual URL" may not refer to a real file, but may contain information that points to an alternate DBFX command file.

In all cases, the request environment may be modified by commands in a real or virtual DBFX command file.

After the DBFX command file has been processed, the environment is handed off to the DBFX Client manager.

(Note - the DBFX command "file" is processed during the RunDBFXInterpreter phase of server request handling)

Cache

There are no cache design notes at this time, as the design is still in flux.

DBFX Env_Variables.txt
Ben Wyckoff

Updated: [REDACTED]

This document contains names (and some semantics) of the environment variables, DBFX Script Tag and attribute names, and SSI Tag Handler tag and attribute names used during DBFX processing.

It is intended that this document be reviewed with an eye towards renaming many of the symbols to improve overall clarity.

There are three broad categories of symbol names that the end user sees: DBFX Script Tag and Attribute names (DBFX Tag Names), DBFX Script Variable Names (DBFX Var Names), and DBFX SSI Tag Handler Tag and Attribute Names (SSI Tag Names). The DBFX Var Names are further broken down into categories. (Yet another class of symbols is constants - I'll lump them in with DBFX Var Names...)

The naming conventions should be similar, but they are discussed separately below.

SSI Tag Names

DBFX registers "tag handlers" with WebSTAR SSI, and SSI calls the registered function when it encounters the specified tags. All of the attribute/value pairs in the tag are passed through to DBFX but some of them have special semantics and are copied/coerced into other internal environment variables.

Online documentation is currently at <<http://www.clearway.com/dbfx/docs/SSI.html>>

Tag Names:

EXEC_DBFX
EXEC_DBFX_SSI - like EXEC_DBFX, except SSI processes the results

The above two tags take all of their parameters as attribute/value pairs - there is no closing tag.

EXEC_DBFX_SCRIPT and /EXEC_DBFX_SCRIPT
EXEC_DBFX_SCRIPT_SSI and /EXEC_DBFX_SCRIPT_SSI

The _SCRIPT tag names do accept attribute/value pairs, but also interpret the text between the begin and end tags as the DBFX script to be executed. The _SSI variant causes SSI to process the results for additional SSI tags.

The EXEC_DBFX* tag handler sets all of the attribute/value pairs in the environment as "FORM.attrname" variables. Some of the attributes are special cases as defined below:

PATH="dbfx_file_name" - the "SCRIPT_NAME" of the file-based DBFX script to execute.
(does not apply to the _SCRIPT variants)

STARTBEFORE="delimiter_text"
STARTAFTER="delimiter_text"
ENDBEFORE="delimiter_text"
ENDAFTER="delimiter_text"

The start/end attributes are used internally to control how much of the entity is returned to SSI from the tag handler. Note that the start/end variables may be set directly in the _SCRIPT variants using <SET STARTBEFORE="..."> commands in the script body as well as passed as attribute/value pairs in the tag body.

DBFX Tag Names

The DBFX Script Language is documented online at

<<http://www.clearway.com/dbfx/docs/ScriptReference.html>>

<DISPLAY_MESSAGE "text">

<SET name = expression>

<IF expression> ... <ELSE> ... <ENDIF>
(also </IF> as synonym for <endif>)

<DECACHE "match_string">

<DECACHE_REGEX "regular_expression_string">

<PRECACHE HREF="url" METHOD="method" POSTARGS="post_arg_string" ...>

The ... means you can also specify arbitrary attribute/value pairs in the PRECACHE tag. DBFX assigns the value into a variable with the same name as the attribute (NOT as FORM.attrname). This is particularly useful for specifying cache-control values for the individual precache request, such as DBFX.CACHE.TTL.

<INSERT_CONTENT HREF="url" METHOD="method" POSTARGS="post_arg_string" ...>

The ... means the same thing as in PRECACHE. In addition the START/END tags used in EXEC_DBFX are valid here as well.

<RETRIEVE_CONTENT HREF="url" METHOD="method" POSTARGS="post_arg_string" ...>

This is like INSERT_CONTENT (including the START/END tags), plus the "INTOVAR" attribute name is special - it tells DBFX what env variable to store the result in.

<INSERT_STRING "value">

<REDIRECT HREF="url">

Internally (i.e., not documented), DBFX also accepts "URI", "URL", "LOCATION" as synonyms for the "HREF" attribute name.

<ON_ERROR ...>

// attribute names are not yet documented online...

<ON_ERROR ACTION="REDIRECT" | "SERVE_FROM_CACHE"
URI=xxx>

Synonyms for URI are "URL" and "LOCATION"

<SYSBEEP>

<MATCH_REGEX ...>

// attribute names are not yet documented online...

// in fact, the regexp behavior and is not yet documented online either
C4-based attributes: "SRC", "REGEXP", "INTO",

DBFX custom attr "IGNORECASE" - causes DBFX to (incorrectly) ignore case

when doing the regexp match - defaults to "FALSE"
INTO defaults to "MATCH.", and defines the prefix for the regexp match vars

<INCLUDE "path">
(DBFXINCLUDE is a synonym for INCLUDE)

<DEFINE _SITE UINAME="name" PATH="siteroot" SCRIPTSPATH="scriptsfolder"
HOSTNAMES="hostname__list">

<REPEAT> and </REPEAT>
// completely undocumented in DBFX (but identical to C4 usage)
// needed for Admin, might as well document as part of the DBFX Script Language.

DBFX Var Names

This major section encompasses DBFX script environment variable names and values. There are 3 main types of DBFX scripts: Automatic scripts, Filter Scripts, and Request Scripts.

Automatic scripts include startup, shutdown, flush, every-minute etc and precache. The STARTUP and SHUTDOWN scripts run in the global environment by design. All other scripts run in a temporary env that has the global env as a parent.

Filter Scripts run at W*API filter time, and do not generate content.

Request Scripts run at "CGI" time, and are responsible for directly or indirectly generating content to return to the client.

Global Variables

Cache Control

(documented online at <http://www.clearway.com/dbfx/docs/CacheControl.html>)

There are global variables that determine default cache behavior, and there are variables that can modify cache behavior on a per-request or per-entity basis.

D

<!--
